What is ventilation? respiration?

Ventilation is the process of moving air in and out of the lungs. Respiration is the process during which the exchange of oxygen (O₂) and carbon dioxide (CO₂) occurs in the alveoli of the lungs. The alveoli are small air sacs at the end of the bronchial tree in the lungs, and it is through the walls of these air sacs that O₂ diffuses into the blood and CO₂ diffuses out of the blood. Ventilation is a constant process of maintaining the proper balance between the two.

What is a ventilator?

A ventilator, also known as a respirator, is the equipment used to mechanically assist breathing by delivering air to the lungs. Many people may be familiar with ventilators in the hospital setting, such as the ICU, where large complex acute care ventilators are used. The ventilators used in the home are small, lightweight and portable; they can be mounted on wheelchairs or carts or put on a bedside stand. Most of these operate on household electric current—some have internal batteries—and can be operated with external batteries. It is advisable to have a backup battery or even a generator readily available in case of power outages or emergencies.

How does mechanical ventilation work?

The diaphragm is the primary muscle for inspiration, along with the intercostal muscles between the ribs. Other muscles of the chest, neck and shoulders play smaller roles. When these breathing muscles are weakened or paralyzed, breathing becomes difficult or impossible. A mechanical ventilator can take over the act of breathing completely or make breathing easier by assisting weakened respiratory muscles.

The muscles of the abdomen are important for breathing out and for an effective cough. Weak expiratory muscles result in impaired cough and inability to clear secretions that can lead to respiratory infections and pneumonias. In certain neuromuscular diseases, the bulbar muscles—those responsible for swallowing, speech and coughing—can become progressively impaired. Cough can be assisted by the use of manual techniques such as lung volume recruitment and breath-stacking and/or mechanical devices such as the CoughAssist®.

How did mechanical ventilation develop?

The iron lung or “tank” was the first effective form of mechanical ventilation, and one of the earliest iron lungs, often used to resuscitate drowning victims, dates from 1838. A century later, in the 1930s, improvements in the iron lung made widespread use of mechanical ventilation possible, particularly during the polio epidemics.

Positive pressure ventilators developed as a more effective breathing option to the larger, bulkier negative pressure devices. Since the 1980s, computer technology has enabled manufacturers to produce even smaller, lightweight ventilators that are easier to transport and operate, and are better suited for people living at home.

What is negative pressure ventilation?

When the pressure around the chest is negative—lower than atmospheric pressure—the chest expands to allow air to enter the nose and mouth. Iron lungs enclose the whole body, except for the head, and create pressure changes between the chest and the encasing shell of the unit.

Other forms of negative pressure ventilation, also known as body ventilators, include the chest shell or cuirass, Nu-Mo suit and Pulmo-wrap. The Porta-Lung™ is a smaller and more mobile version of the iron lung that is still used by a small number of people.

A technologically advanced form of negative pressure ventilation called biphasic cuirass ventilation (BCV) controls both the inspiratory and expiratory phases of breathing. Higher frequencies and tidal volumes allow for higher minute ventilation.

The following equipment specifications are for negative pressure ventilators currently on the markets. There is no “standard” form for specifications. American and European manufacturers differ in the technical information that they provide about their products. Alarms must be a certain volume. Minimum and maximum alarm volume is regulated.

KEY:

① = available only in USA ② = available only outside USA ③ = available worldwide

Hayek RTX (Biphasic cuirass ventilation)

United Hayek Medical, www.unitedhayek.com ③

Pediatric use > 5 kg

Also used as cough assistant

Modes: Continuous negative; mandatory control;
 respiratory synchronized
Rate: 6-1200 cycles per minute
Maximum inspiratory pressure: -50 cm H₂O
Maximum expiratory pressure: +50 cm H₂O
I:E ratio: 1:6 - 6:1
AC voltage: 110-230, 50-60 Hz
External battery: 12 VDC
Dimensions: 370 mm W x 260 mm D x 180 mm H
Weight: 9 kg

Pegaso V

Dima Italia S.r.l., www.dimaitalia.com ②

Rate: 5-50 CPM
Negative pressure: Variable from -5 to -99 cm H₂O
Positive/negative
 pressure E: Variable from +99 to -25 cm H₂O
AC voltage: 115V/230V, 50-50 Hz, 400 VA
Dimensions: 30 cm H x 32 cm W x 25 cm D
Weight: 17 lbs.
Alarms: High/low respiratory pressure, power failure,
 mechanical failure

Porta-Lung™

Porta-Lung, Inc., www.porta-lung.com

(Discontinued; still in use; repairs available)

Breathing rate: 4-60 BPM
Pressure: -60 to +20 cm H₂O
Sizes: X-small, small, medium and large
AC voltage: 120 VAC
External battery: 12 VDC
Weight: 72 lbs-138 lbs
Alarms: Low pressure

What is a pneumobelt?

The pneumobelt, also known as an exsufflation belt, consists of an air bag or bladder inside a cloth corset that is worn around the abdomen and lower chest. The pneumobelt is connected by tubing to a positive pressure ventilator that alternately inflates and deflates the bladder.

As the belt inflates, the abdominal contents are compressed and the abdomen rises, forcing air out of the lungs. When the belt deflates, the diaphragm is lowered and inhalation occurs passively. Because the pneumobelt works with gravity, it is most effective in the sitting and standing positions and should not be used at night in the supine position. The pneumobelt is powered by a volume or combination/multi-mode ventilator. It is available as needed from Philips Respironics. Contact the area representative.

An exsufflation belt is also made in Italy by Dima Italia S.r.l. The LunaBelt (a device) applies IAPV (Intermittent Abdominal Pressure Ventilation) through the use of a defined corset “exsufflation belt” which is available in four sizes.

What is positive pressure ventilation?

Positive pressure—higher than atmospheric pressure—pushes air into the lungs. It can be administered either noninvasively via a wide variety of interfaces (nasal, facial and oral masks, nasal pillows, or mouthpieces), with tubing attaching the interface to the ventilator or invasively via tracheostomy.

Examples of equipment that deliver positive pressure ventilation are bilevel positive airway pressure ventilators, pressure support ventilators and volume ventilators, and combination/multi-mode ventilators.

The high flow of air from positive pressure may cause dryness in the nasal passages and upper airway, and humidifiers may help relieve symptoms of nasal stuffiness, dry mouth and thick nasal secretions. An integrated humidifier is a feature of some ventilators.

What is CPAP?

CPAP (continuous positive airway pressure) provides a continuous flow of air at a constant pressure for both inhalation and exhalation to keep the airway open during sleep. It is the standard of treatment for obstructive sleep apnea, during which the muscles of the throat collapse and block the airway. Auto-titrating CPAP units or APAPs deliver varying pressures based on the detection of sleep-disordered breathing events; the pressure can change breath-by-breath. A nasal or facial mask, connected by tubing to the CPAP unit, is worn during the night.

What is a bilevel positive airway pressure ventilator?

Bilevel ventilators were developed by modifying CPAP so that both inspiratory positive airway pressure (IPAP) and expiratory positive airway pressure (EPAP) could be delivered. The IPAP/EPAP settings can be adjusted separately.

People with neuromuscular disorders and weak diaphragmatic muscles may have difficulty breathing in and may need IPAP set higher than EPAP, e.g. IPAP of 14, EPAP of 3. The difference between IPAP and EPAP is called the span, and in these cases, should be at least 10.

Bilevel ventilators are made by several manufacturers. BiPAP® was the name patented and registered by Respironics, Inc., and many bilevels have been incorrectly referred to as BiPAPs.

Bilevels are used primarily during the night with a noninvasive facial, nasal or oral mask, or nasal pillows. Some people use their bilevels continuously, but in the USA, the FDA has not approved them for 24-hour use in the home. They are also not approved for use by people who have tracheostomies.

What is a bilevel positive airway pressure ventilator? (continued)

Some physicians prescribe them for infants and children, particularly in developing countries because the bilevel ventilators are more affordable and available than volume, pressure, or combination/multi-mode ventilators.

The bilevel modes are:

- “S” for spontaneous breathing patterns that the unit senses and then switches between prescribed pressures.
- “T” for timed breaths that are delivered at a preset rate.
- “S/T” for spontaneous/timed. The unit switches to a timed mode (also known as a backup rate) when breaths are not spontaneously initiated by the individual. People with neuromuscular disorders should use a bilevel ventilator with a backup rate so that breaths are initiated for them.

The advantages of bilevel ventilators are: small size, light weight and portability, lower cost, and compensation for leaks from masks. Disadvantages include lack of internal batteries, no or few alarms, inadequate pressures for some people, higher electricity operating costs, and discomfort from EPAP. Many of the combination/multi-mode ventilators can provide bilevel ventilation.

The following equipment specifications are for bilevel ventilators currently on the markets. There is no “standard” form for specifications. American and European manufacturers differ in the technical information that they provide about their products. Alarms must be a certain volume. Minimum and maximum alarm volume is regulated.

What is a volume-cycled ventilator?

Volume-cycled ventilators deliver a preset volume of air in a constant flow during inspiration. Volume ventilators can deliver higher volumes and pressures than bilevel units; the volume remains constant despite interface leaks. The pressure limit can be adjusted by increasing the volume and lowering the high-pressure alarm. Volume-cycled ventilators can be used for breath stacking (adding one breath to another without exhaling) to enable deeper breaths for improved cough. They also have alarms and internal batteries, but they are larger, heavier and more expensive than bilevel units, although some use less electricity to operate. If an individual needs 24-hour ventilation, a volume ventilator is recommended because it is approved by the FDA for this purpose and has the necessary safety features.

Mode Definitions

Control: Delivers only controlled breaths at specified tidal volume and prescribed respiratory rate. Ventilator is triggered by pre-set machine rate, and the individual cannot take any spontaneous breaths.

Assist/Control: Allows individual to initiate/trigger a machine-assisted breath and to take additional breaths at prescribed tidal volume.

SIMV (Synchronized Intermittent Mandatory Ventilation): Prescribed tidal volume and respiratory rate but individual can breathe spontaneously in between delivered breaths.

PEEP (Positive End Expiratory Pressure): Airway pressure is maintained at the end of the ventilator breaths to increase volume of air remaining in the lungs at the end of expiration.

IPPB (Intermittent Positive Pressure Breathing): Intermittent delivery of deep insufflations.

Sigh: Provides an increased amount of volume at intervals to simulate a normal sigh breath.

The following equipment specifications are for volume-cycled ventilators currently on the markets. There is no "standard" form for specifications. American and European manufacturers differ in the technical information that they provide about their products. Alarms must be a certain volume. Minimum and maximum alarm volume is regulated.

What is a pressure support ventilator? What is pressure control?

Pressure support ventilators supplement the inspiratory effort of individuals who can breathe spontaneously by providing a preset amount of positive airway pressure throughout the complete inspiration. The tidal volume can vary from breath to breath. Pressure control means that the ventilator, rather than the individual, controls the breathing rate. Pressure control maintains a preset inspiratory pressure.

The following equipment specifications are for pressure support ventilators currently on the markets. There is no “standard” form for specifications. American and European manufacturers differ in the technical information that they provide about their products. Alarms must be a certain volume. Minimum and maximum alarm volume is regulated.

What is a combination or multi-mode ventilator?

The current generation of ventilators can provide many modes of ventilation: pressure support, pressure control, volume control, bilevel pressure or CPAP.

The following equipment specifications are for combination ventilators currently on the markets. There is no “standard” form for specifications. American and European manufacturers differ in the technical information that they provide about their products. Alarms must be a certain volume. Minimum and maximum alarm volume is regulated.

Ventilators for infants and children

The choice of a ventilation system in infants and children involves several factors such as the child's age; degree of respiratory impairment; need for positive end expiratory pressure (PEEP), pressure support, and higher respiratory rates; and the resources and support systems at home.

Infants who are born prematurely often need a ventilator to help them breathe while in the Neonatal Intensive Care Unit (NICU). Others may have progressive and severe muscle weakness or severe aspiration that caused lung injury. These children usually require a tracheostomy to establish an artificial airway and to protect their developing airways.

Children's ventilatory needs can vary from full respiratory support to partial respiratory support with some ventilator-free time. In children who can initiate a breath and only require night-time support, the use of noninvasive ventilation is increasing. Popular ventilators for pediatric use include the Newport HT50® and Newport HT70®, LTV® series, Trilogy100, and Stellar™ 100 and 150™ with Pixi® mask system. The Nippy Junior + is the only ventilator **specifically manufactured** for infants and children (for use in the UK and Europe). In many developing countries, bilevel ventilators are often the only ventilators that are affordable and available to use.

Nippy Junior +

B & D Electromedical, www.nippyventilator.com ②

Mode:	Pressure control, pressure support, CPAP, IPPV (NIV and tracheostomy)
Pressure range:	0-30 cm H ₂ O IPAP; 3-20 cm H ₂ O EPAP
BPM:	6-60
Maximum flow rate:	200L/min
AC voltage:	100-240 V, 47-63 Hz
Internal battery:	4-12 hours depending on settings and leak
External battery:	24 VDC, 4-12 hours depending on settings and leak
Dimensions:	30 L x 22 W x 13 H cm
Weight:	4.5 kg
Alarms:	Low/high pressure, low/high flow, low/empty battery, malfunction, disconnect, power failure
Humidifier:	External
O:	No

Which method and ventilator should be used?

The choice of ventilator can be made by an individual's primary physician, or the primary physician may make a referral to a pulmonologist (also known as a respirologist) who specializes in breathing-related disorders and lung conditions, and often sleep medicine. Some physical medicine and rehabilitation physicians, known as physiatrists, and some neurologists may also specialize in breathing disorders. In some countries only a pulmonologist can prescribe a ventilator.

After careful evaluation and pulmonary function tests to assess breathing and lung function and capacity (and sometimes a sleep study), the physician recommends a type of ventilator and appropriate interfaces. Individuals who need to use ventilation only at night have different equipment requirements than those who need to use a ventilator around the clock. Sometimes an individual may not be comfortable with a specific ventilator or interface and may need to change them in order to find the most comfortable and effective system.

Some ventilator users alternate modes and interfaces during the day and night.

What if something goes wrong with the ventilator?

Ventilator users and their caregivers must be prepared for equipment failure, disconnects, and power outages, especially if using 24-hour ventilation, in which case a backup ventilator and generator are prudent. Practicing regular safety drills helps prepare for emergencies. Keeping a manual resuscitator, such as an Ambu® bag, handy at all times is strongly advised.

Where do I find information about ventilator safety and reported incidents?

The FDA maintains a database for reports of problems with medical equipment, including ventilators, that is updated continually.
